

PROBLEM STATEMENT:

Every music listener has experienced both sides of this pattern — a song that was inescapable for two weeks, on every reel, every playlist, every radio segment, and then completely gone; and another that you barely noticed when it released, only to find yourself still listening to it six months later. These are two genuinely different relationships between a song and its audience, but the charts treat them the same way: a peak rank and a streams number, with no record of how that popularity actually unfolded over time. For the Indian streaming market specifically where Bollywood release weekends, Punjabi pop, Tamil and Telugu film soundtracks, independent singer-songwriters, and devotional music all compete on the same weekly chart this difference in listening behaviour has never been systematically measured or visualized.

PROJECT COMPONENTS:

1. **Data Preparation & Modeling (Python):** Clean and transform the 54 weekly Spotify CSV files for Indian charts analysis, handling date normalization and trajectory classification.
2. **Data Analysis (SQL):** Structure the raw chart data into queryable tables, simulate song lifecycle transactions, and run queries to extract insights on various engagement patterns, customer (listener) segments, and popularity drivers.
3. **Visualization & Insights (Power BI):** Build an interactive dashboard highlighting viral spike trajectories, long-term engagement patterns, and Artist comparisons across the Indian streaming market.
4. **Report and Presentation:** Write a clear project report summarizing key findings on song-audience relationship patterns and actionable recommendations for artists, labels, and platform strategists. Prepare a presentation visually communicating trajectory insights to stakeholders.
